CS100 Introduction to Programming

Lecture 6. Pointers

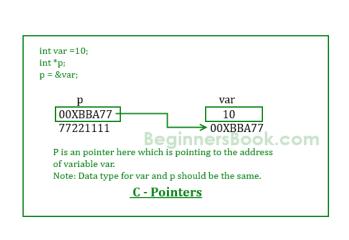

Address and Pointer

Address of a Variable

- What is the address in C?
 - An integer indicating the numerical number of memory storage unit

Note: All numbers in hexadecimal

Usually in binary or hexadecimal format

Cor	nputer	Р	rogrammers	
Address	Content	Name	Type	Value
90000000	00	٦)		
90000001	00	sum	int	000000FF(255 ₁₀)
90000002	00	Sum	(4 bytes)	00000011 (23310)
90000003	FF	1 J	(4 Dyces)	
90000004	FF	age	short	FFFF(-1 ₁₀)
90000005	FF] Juge	(2 bytes)	1111 (110)

		_		

Address Operator (&)

```
#include <stdio.h>
int main(void)
   int num = 5;
   printf("num = %d, &num = %p\n", num, &num);
   scanf("%d", &num);
   printf("num = %d, &num = %p\n", num, &num);
   return 0;
                                  This value is just for illustration,
                                  and may be different for another
                                  run.
```

```
Output:

num = 5, &num = 1024

<u>10</u>

num = 10, &num = 1024
```

Pointer Variables

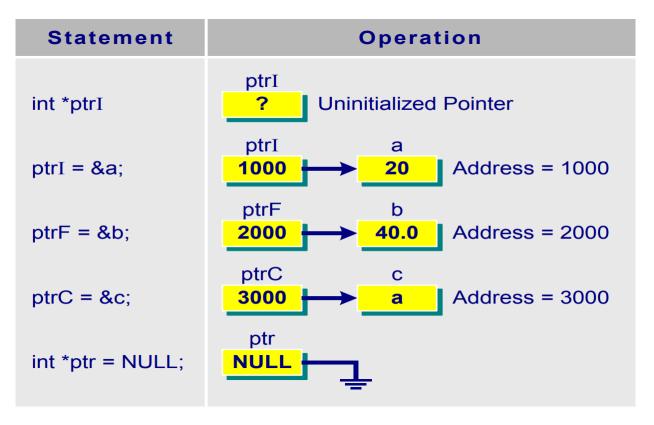

- We may have variables which store the addresses of memory locations of some data objects. These variables are called pointers.
- A pointer variable is declared by dataType
 *pointerName, for example:

The value of a pointer variable is an address.

Pointer Variables

Example:

```
int a = 20; float b = 40.0; char c = 'a';
int *ptrI; float *ptrF; char *ptrC;
ptrI = &a; ptrF = &b; ptrC = &c;
```

Pointer To Pointer

A pointer storing the value of another pointer

```
p1
p2
                              num
                                   12
       #include <stdio.h>
       int main(void)
          float num=12;
          float* p1=#
          float** p2=&p1;
          return 0;
```

Indirection Operators (*)

 The content of the memory location pointed to by a pointer variable is referred to by using the indirection operator *.

• If a pointer variable is defined as ptr, we use the expression *ptr to <u>dereference</u> the pointer to obtain the value stored at the address pointed to by the pointer ptr.

Indirection Operator – Example 1

```
Statement
                                             Operation
#include <stdio.h>
int main(void)
                                      ptr
                                              num
                         ptr = #
                                                    Address = 1024
   int num = 3;
                                      ptr
                                              num
   int *ptr;
                         *ptr = 10;
                                                    Address = 1024
   ptr = #
   printf("num = %d, &num = %p\n", num, &num);
   printf("ptr = %p, *ptr = %d\n", ptr, *ptr);
   *ptr = 10;
   printf("num = %d, &num = %p\n", num, &num);
   return 0;
                        Output:
                        num = 3, &num = 1024
                        ptr = 1024, *ptr = 3
                        num = 10, &num = 1024
```

Indirection Operator – Example 2

```
/* example to show the use of pointers */
#include <stdio.h>
int main(void)
{
   int num1 = 3, num2 = 5;
   int *ptr1, *ptr2;
   ptr1 = &num1; // put the address of num1 into ptr1
   printf("num1 = %d, *ptr1 = %d\n", num1, *ptr1);
   (*ptr1)++; /* increment by 1 the content of the
               memory location pointed to by ptr1 */
   printf("num1 = %d, *ptr1 = %d\n", num1, *ptr1);
   ptr2 = &num2; // put the address of num2 into ptr2
   printf("num2 = %d, *ptr2 = %d\n", num2, *ptr2);
```

Code continues in next slide ...

Output:

```
num1 = 3, *ptr1 = 3
num1 = 4, *ptr1 = 4
num2 = 5, *ptr2 = 5
```

```
*ptr2 = *ptr1; /* copy the content of the location
                pointed to by ptr1 into the
                location pointed to by ptr2 */
printf("num2 = %d, *ptr2 = %d\n", num2, *ptr2);
*ptr2 = 10; /* 10 is copied into the location
                pointed to by ptr2 */
num1 = *ptr2; /* copy the content of the memory
                location pointed to by ptr2
                into num1 */
printf("num1 = %d, *ptr1 = %d\n", num1, *ptr1);
*ptr1 = *ptr1 * 5;
printf("num1 = \%d, *ptr1 = \%d\n", num1, *ptr1);
ptr2 = ptr1; // address in ptr1 copied into ptr2
printf("num2 = %d, *ptr2 = %d\n", num2, *ptr2);
return 0;
```

Output:

```
num2 = 4, *ptr2 = 4

num1 = 10, *ptr1 = 10

num1 = 50, *ptr1 = 50

num2 = 10, *ptr2 = 50
```

Indirection Operator – Example 2

Statement	num1 num2 (addr = 1024) (addr = 2048)	ptr1	ptr2
int num1 = 3, num2 = 5;	3 5		
int *ptr1, *ptr2;	3 5	?	?
ptr1 = &num1	3 5	1024	?
(*ptr1)++;	4 5	1024	?
ptr2 = &num2	4 5	1024	2048
*ptr2 = *ptr1;	4 4	1024	2048
*ptr2 = 10;	4 10	1024	2048
num1 = *ptr2;	10 10	1024	2048
*ptr1 = *ptr1 * 5;	50 10	1024	2048
ptr2 = ptr1;	50 10	1024	1024

Multiple Indirection

```
#include <stdio.h>
int main(void)
  float num=12;
  float* p1=#
  float** p2=&p1;
  printf("the content with indirection once: %f", *p1);
  printf("the content with indirection twice: %f", *(*p2));
  return 0;
```

How function is called?

Entry point

- the first instruction a program is executed
- In C/C++, the main() function

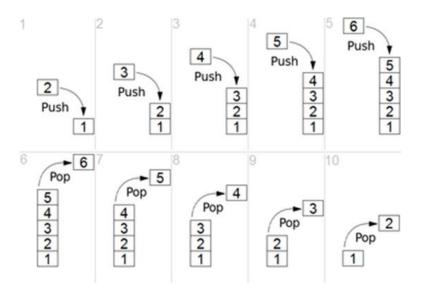

```
int main(void);
int main();
int main(int argc, char **argv);
```

- Loader of operating system will load the program into memory, giving the entry point a specific address
- This marks the transition from load time to run time.

How function is called?

Function (call) stack

- What is a stack?
 - A data structure to store data in a first-in-last-out order
 - Two operations:
 - push (into the stack) / pop (out of the stack)

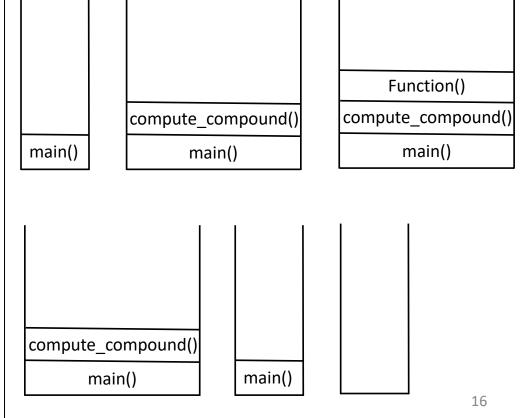

How function is called?

Function call process

With the aid of function call stack, storing pointers

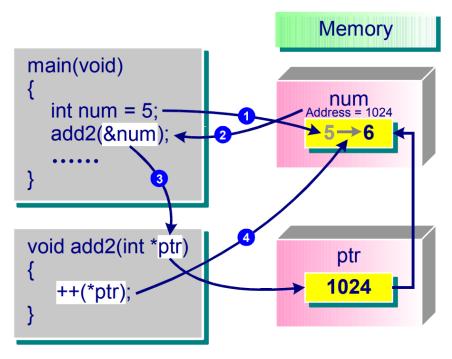

```
#include <stdio.h>
float compute compound(float x);
float function(float x);
void main()
{
    float f=compute compound(10.0);
    printf("the result is: %f\n", f);
    return 0;
float compute compound()
    return exp(function(x));
float function(float x)
{
    return sin(x)*sin(x);
```

Call by Pointer

- Parameter passing between functions has two modes:
 - Call by value
 - Call by pointer
- Call by value: The argument of a function has a local copy when it is passed to the function.
- Call by pointer: The argument of a function shares the same <u>address</u> of the argument variable, no argument copy is performed.
 - Therefore, a change to the value pointed to by the parameter changes the argument value (instantly).

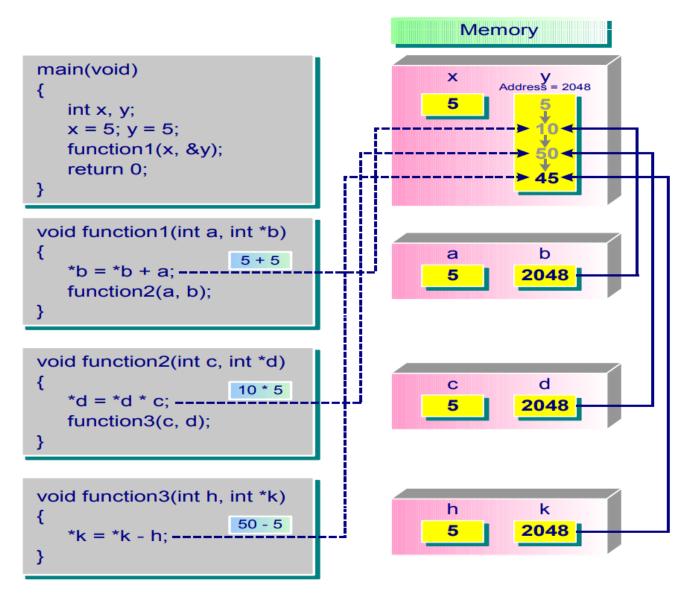

```
#include <stdio.h>
void add2(int *ptr);
int main(void)
   int num = 5;
   // passing the address of num
   add2(&num);
   printf("Value of num is: %d",
          num);
   return 0;
void add2(int *ptr)
   ++(*ptr);
```

Output:

Value of num is: 6

```
#include <stdio.h>
void function1(int a, int *b);
void function2(int c, int *d);
void function3(int h, int *k);
int main(void) {
  int x, y;
  x = 5; y = 5;
                                   /* (i) */
                                   /* (x) */
  function1(x, &y);
  return 0;
void function1(int a, int *b) {     /* (ii) */
  *b = *b + a;
                                  /* (iii) */
  function2(a, b);
                                   /* (ix) */
void function2(int c, int *d) { /* (iv) */
                                 /* (v) */
  *d = *d * c;
  function3(c, d);
                                   /* (viii) */
void function3(int h, int *k) {     /* (vi) */
  *k = *k - h:
                                   /* (vii) */
```

	X	y	a	*b	c	*d	h	*k	remarks
(i)	5	5	ı	-	ı	-	•	ı	
(ii)	5	5	5	5	ı	-	ı	ı	
(iii)	5	10	5	10	ı	1	-	•	
(iv)	5	10	5	10	5	10	•	ı	
(v)	5	50	5	50	5	50	ı	ı	
(vi)	5	50	5	50	5	50	5	50	
(vii)	5	45	5	45	5	45	5	45	
(viii)	5	45	5	45	5	45	ı	ı	
(ix)	5	45	5	45	-	-	-	-	
(x)	5	45	•	-	-	-	-	-	

When to Use "Call by Pointer"?

 When you need to pass more than one value back from a function.

- When using call by value, it results in a large piece of information being copied to the local memory, e.g. passing large arrays.
 - In such cases, for the sake of efficiency, we'd better use call by reference.

Call by Reference

- Call by reference: The argument of a function is another name of the same variable, no argument copy is performed.
 - Therefore, a change to the value of the parameter changes the argument value (instantly).

Declaration of a reference variable

```
float a=10.0;
float& b=a; //reference variable should be initialized.

b=15;
printf("the value of a is: %f\n",a);
```

Example: multiple function return values

Get the area and circumference of a circle

```
#include <stdio.h>
#define PI 3.1415926
void GetCircleInfo(float R, float *area, float *circum);
                                        /*Using pointer implementation*/
int main(void) {
  float R=0, area=0, circum=0;
  scanf("Input circle radius: %f", &R);
  GetCircleInfo(R, &area, &circum);
  printf("The circle area is :%f\n", area);
  printf("The circle circumference is :%f\n", area);
  return 0;
void GetCircleInfo(float R, float *area, float *circum){
   *area=PI*R*R;
   *circum=2*PI*R;
```

Example: multiple function return values

Get the area and circumference of a circle

```
#include <stdio.h>
#define PI 3.1415926
void GetCircleInfo(float R, float &area, float &circum);
                                        /*Using reference implementation*
int main(void) {
  float R=0, area=0, circum=0;
  scanf("Input circle radius: %f", &R);
  GetCircleInfo(R, area, circum);
  printf("The circle area is :%f\n", area);
  printf("The circle circumference is :%f\n", area);
  return 0;
void GetCircleInfo(float R, float *area, float *circum){
   area=PI*R*R;
   circum=2*PI*R;
```

Function Pointers

- A subroutine pointer or procedure pointer
 - A pointer that points to a function
 - Points to executable code within memory

```
#include <stdio.h> /* for printf */
#include <string.h> /* for strchr */

double cm_to_inches(double cm) {
    return cm / 2.54;
}

// "strchr" is part of the C string handling (i.e., no need for declaration)
// See https://en.wikipedia.org/wiki/C_string_handling#Functions

int main(void) {
    double (*func1)(double) = cm_to_inches;
    char * (*func2)(const char *, int) = strchr;
    printf("%f %s", func1(15.0), func2("Wikipedia", 'p'));
    /* prints "5.905512 pedia" */
    return 0;
}
```

Function Pointer as Function Parameter

```
1 #include <math.h>
 2 #include <stdio.h>
 4 // Function taking a function pointer as an argument
 5 double compute sum(double (*funcp)(double), double lo, double hi) {
       double sum = 0.0;
       // Add values returned by the pointed-to function '*funcp'
 8
 9
       int i:
10
       for(i = 0; i <= 100; i++) {
           // Use the function pointer 'funcp' to invoke the function
11
           double x = i / 100.0 * (hi - lo) + lo;
12
           double y = funcp(x);
13
14
           sum += y;
15
       return sum / 101.0;
16
17 }
18
19 double square(double x) {
        return x * x;
20
21 }
22
```

```
23 int main(void) {
       double sum;
25
26
      // Use standard Library function 'sin()' as the pointed-to function
27
       sum = compute sum(\sin, 0.0, 1.0);
28
       printf("sum(sin): %g\n", sum);
29
30
      // Use standard Library function 'cos()' as the pointed-to function
       sum = compute sum(cos, 0.0, 1.0);
31
32
       printf("sum(cos): %g\n", sum);
33
34
       // Use user-defined function 'square()' as the pointed-to function
35
       sum = compute sum(square, 0.0, 1.0);
       printf("sum(square): %g\n", sum);
37
38
       return 0;
39 }
```
