# **Tree Indexes**

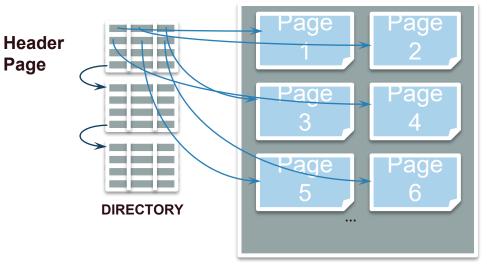

R & G - Chapter 10

### Reminder on Heap Files

**Page** 

- Two access APIs:
  - fetch by recordId (pageId, slotId)
  - scan (starting from some page)

#### Wouldn't it be nice...

- ...if we could look things up by value?
- Toward a Declarative access API
- But ... efficiency?
  - "If you don't find it in the index, look very carefully through the entire catalog."
  - —Sears, Roebuck, and Co., Consumers' Guide, 1897

#### We've seen this before

- Data structures ... in RAM:
  - Search trees (Binary, AVL, Red-Black, ...)
  - Hash tables

- Needed: disk-based data structures
  - "paginated": made up of disk pages!

#### Index

An **index** is data structure that enables fast **lookup** and **modification** of **data entries** by **search key** 

- Lookup: may support many different operations
  - Equality, 1-d range, 2-d region, ...
- Search Key: any subset of columns in the relation
  - Do not need to be unique
    - —e.g. (firstname) or (firstname, lastname)

#### Index Part 2

An **index** is data structure that enables fast **lookup** and **modification** of **data entries** by **search key** 

- Data Entries: items stored in the index
  - Assume for today: a pair (k, recordId) ...
    - Pointers to records in Heap Files!
    - Easy to generalize later
- Modification: want to support fast insert and delete

Many Types of indexes exist: B+-Tree, Hash, R-Tree, GiST, ...

# Simple Idea?

Input Heap File

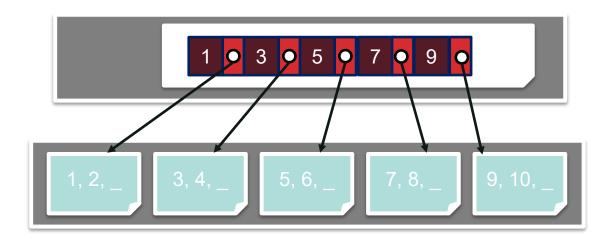

- Step 1: Sort heap file & leave some space
  - Pages physically stored in logical order (sequential access)
  - Do we need "next" pointers to link pages?
    - No. Pages are physically sorted in logical order

- **Step 2**: Build the index data structure over this...
  - Why not just use binary search in this heap file?
    - Fan-out of 2 → deep tree → lots of I/Os
    - Examine entire records just to read key during search

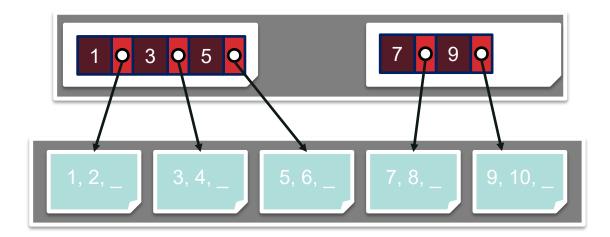

# Build a high fan-out search tree

- Start simple: Sorted (key, page id) file
  - No record data
  - Binary search in the key file. Better!
  - Forgot: Need to break across pages!

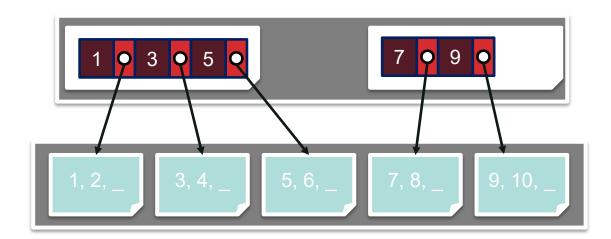

# Build a high fan-out search tree

- Start simple: Sorted (key, page id) file
  - No record data
  - Binary search in the key file. Better!
  - Forgot: Need to break across pages!

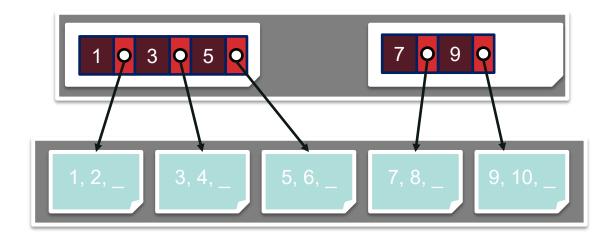

# Build a high fan-out search tree Part 2

- Start simple: Sorted (key, page id) file
  - No record data
  - Binary search in the key file. Better!
  - Complexity?

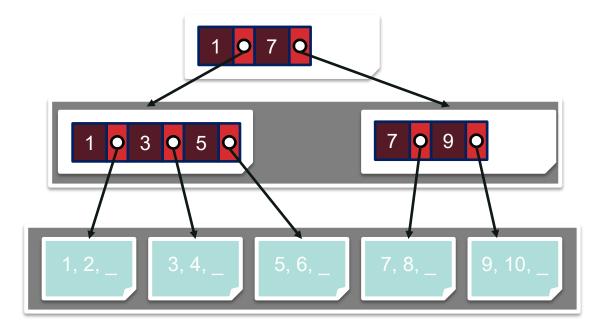

### Build a high fan-out search tree Part 3

- Start simple: Sorted (key, page id) file
  - No record data
  - Binary search in the key file. Better!
  - Complexity: Still binary search, just a constant factor smaller input

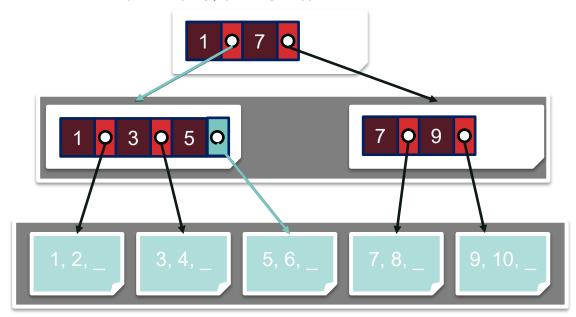

# Build a high fan-out search tree Part 4

- Recursively "index" key file
- Key Invariant:
  - Node [..., (K<sub>L</sub>, P<sub>L</sub>), (K<sub>R</sub>, P<sub>R</sub>), ... ] → All tuples in range K<sub>L</sub> <= K < K<sub>R</sub> are in tree P<sub>L</sub>

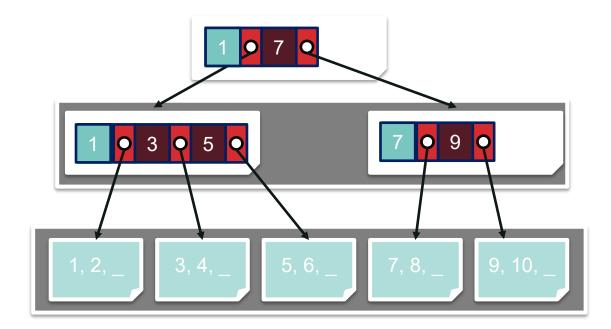

### Search a high fan-out search tree

- Searching for 5?
  - Binary Search each node (page) starting at root
  - Follow pointers to next level of search tree
- Complexity? O(log<sub>F</sub>(#Pages))

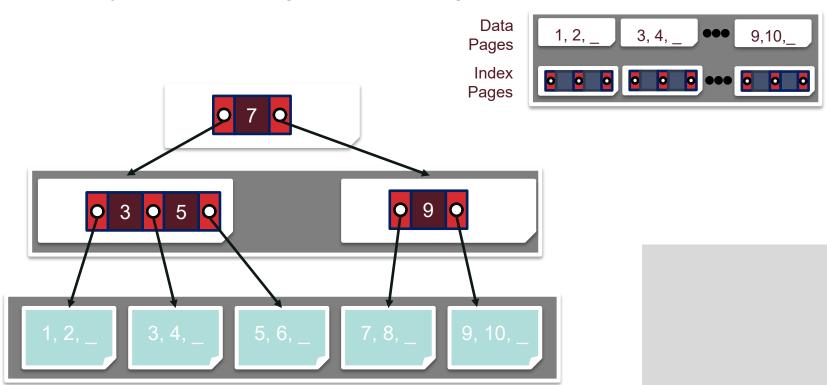

# Left Key Optimization?

- Optimization
  - Do we need the left most key?

# Build a high fan-out search tree

Disk Layout? All in a single file, Data Pages first.

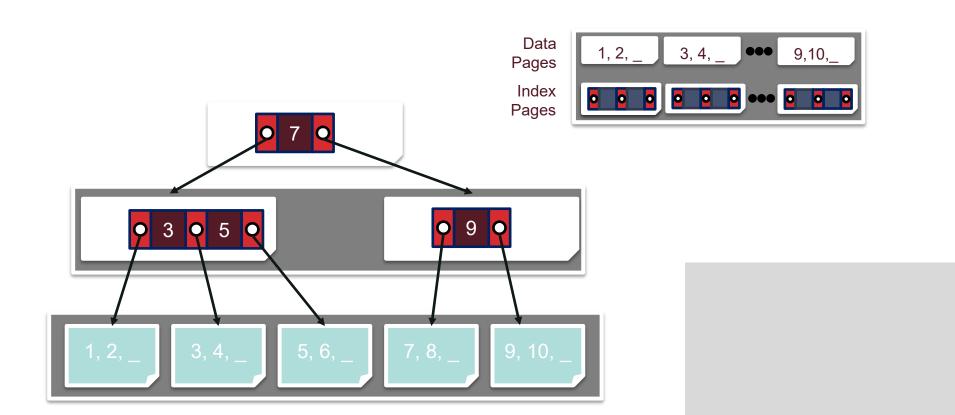

#### Status Check

Some design goals:

Fast sequential scan? 9,10, High Fan-o Support in **ISAM** Indexed Sequential **Access Method** (Early IBM Indexing Technology)

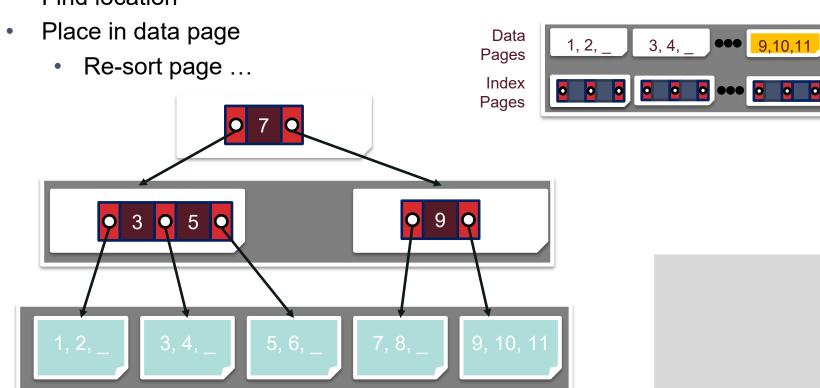

Indexed File

# Insert 11, Before

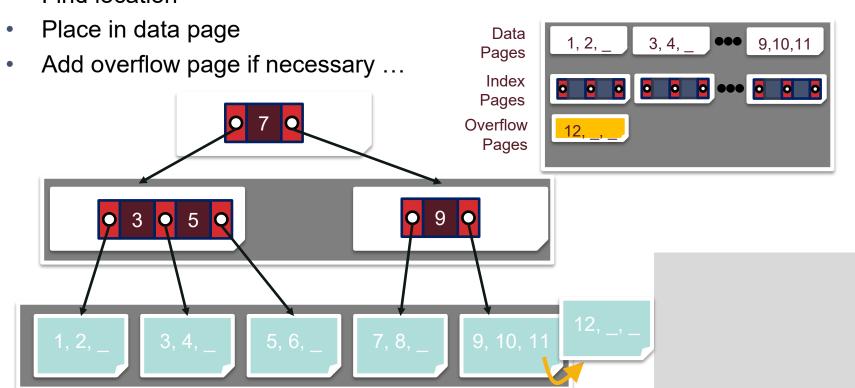

### Insert 11, After

Find location

#### Insert 12?

Find location

# Recap: ISAM

- Data entries in sorted heap file
- High fan-out static tree index
- Fast search + good locality
  - Assuming nothing changes
- Insert into overflow pages

#### A Note of Caution

- ISAM is an old-fashioned idea
  - Introduced by IBM in 1960s
  - B+ trees are usually better, as we'll see
    - Though not always (← we'll come back to this)
- But, it's a good place to start
  - Simpler than B+ tree, many of the same ideas
- Upshot
  - Don't brag about ISAM on your resume
  - Do understand ISAM, and tradeoffs with B+ trees

### **B+-TREE**

#### Enter the B+ Tree

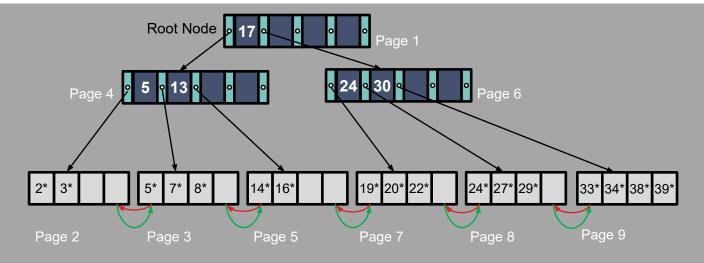

- Similar to ISAM
  - Same interior node structure
    - Key, Page Ptr> pairs with same key invariant
  - Same search routine as before

#### Dynamic Tree Index

- Always Balanced
- Support efficient insertion & deletion
  - Grows at root not leaves!
- "+"? B-tree that stores data entries in leaves only

### Example of a B+ Tree

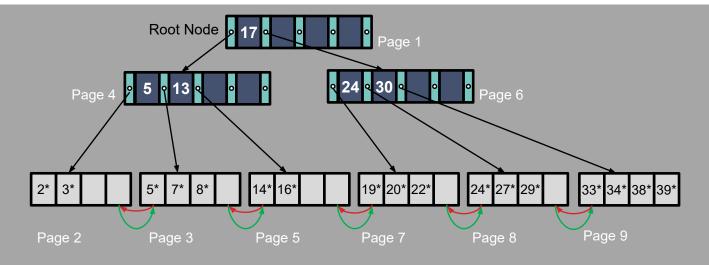

- Occupancy Invariant
  - Each interior node is at least partially full:
    - d <= #entries <= 2d</li>
    - d: order of the tree (max fan-out = 2d + 1)
- Data pages at bottom need not be stored in logical order
  - Next and prev pointers

# Sanity Check

What is the value of d?

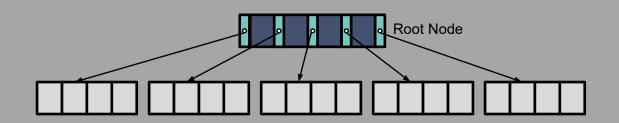

What about the root?

The root is special

Why not in sequential order?

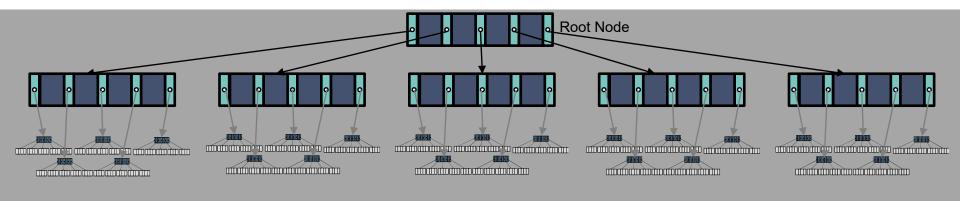

Data pages allocated dynamically

### B+ Trees and Scale

- How big is a height 1 B+ tree
  - $d = 2 \rightarrow Fan-out?$
  - Fan-out = 2d + 1 = 5
  - **Height 1:** 5 x 4 = 20 Records

### B+ Trees and Scale Part 2

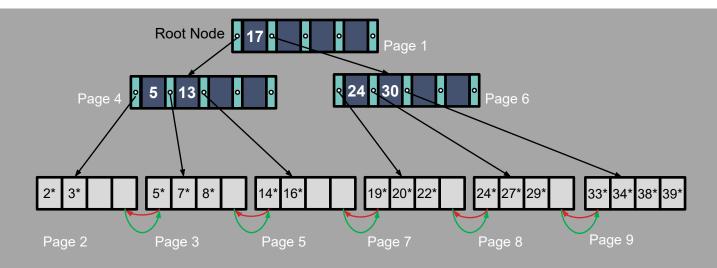

- How big is a height 3 B+ tree
  - $d = 2 \rightarrow Fan-out?$
  - Fan-out = 2d + 1 = 5
  - Height 3: 5<sup>3</sup> x 4= 500 Records

#### B+ Trees in Practice

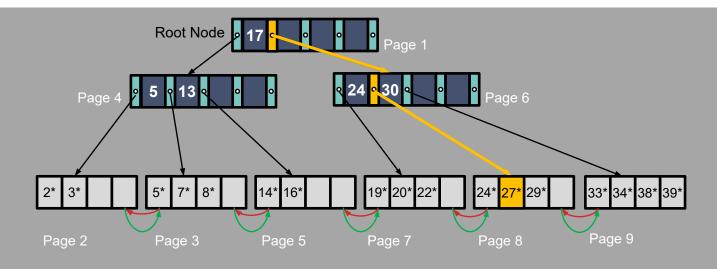

- Typical order: 1600. Typical fill-factor: 67%.
  - average fan-out = 2144
  - (assuming 128 Kbytes pages at 40Bytes per record)
- At typical capacities
  - Height 1: 2144<sup>2</sup> = **4,596,736 records**
  - Height 2: 2144<sup>3</sup> = 9,855,401,984 records

# Searching the B+ Tree

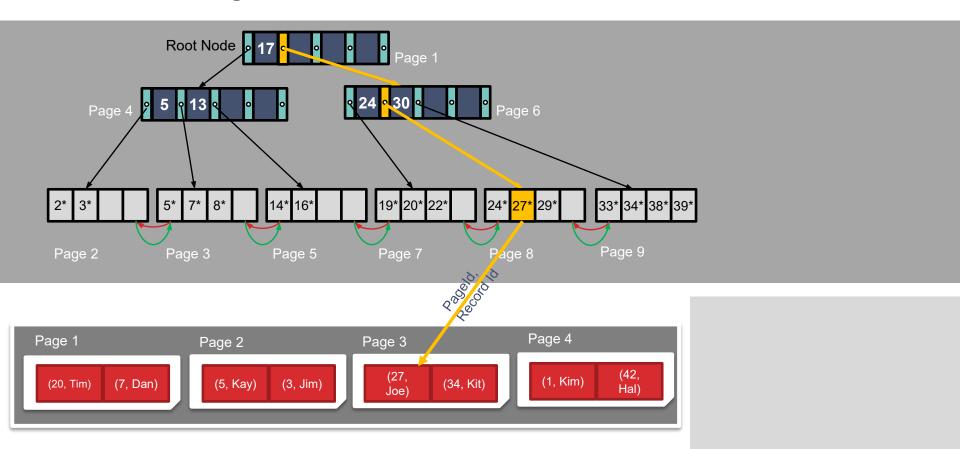

- Same as ISAM
- Find key = 27
  - Find split on each node (Binary Search)
  - Follow pointer to next node

# Searching the B+ Tree: Find 27

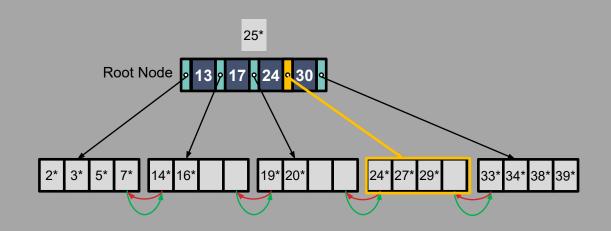

- Same as ISAM
- Find key = 27
  - Find split on each node (Binary Search)
  - Follow pointer to next node

# Searching the B+ Tree: Fetch Data

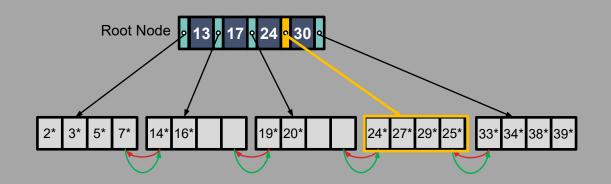

# Inserting 25\* into a B+ Tree Part 1

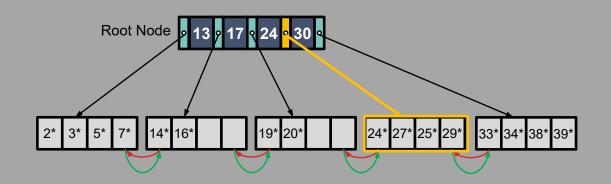

Find the correct leaf

### Inserting 25\* into a B+ Tree Part 2

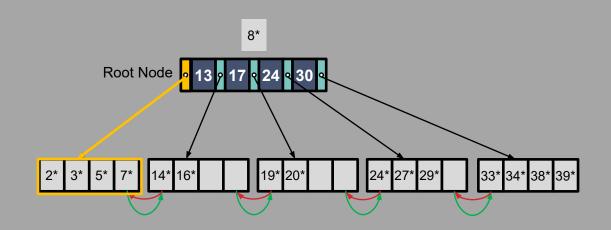

- Find the correct leaf
- If there is room in the leaf just add the entry

### Inserting 25\* into a B+ Tree Part 3

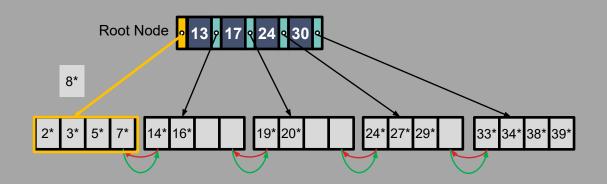

- Find the correct leaf
- If there is room in the leaf just add the entry
  - Sort the leaf page by key

### Inserting 8\* into a B+ Tree: Find Leaf

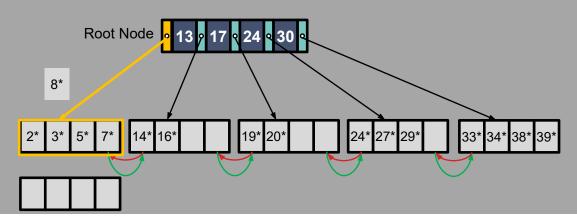

Find the correct leaf

### Inserting 8\* into a B+ Tree: Insert

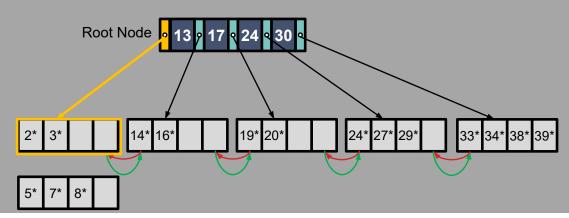

- Find the correct leaf
  - Split leaf if there is not enough room

# Inserting 8\* into a B+ Tree: Split Leaf

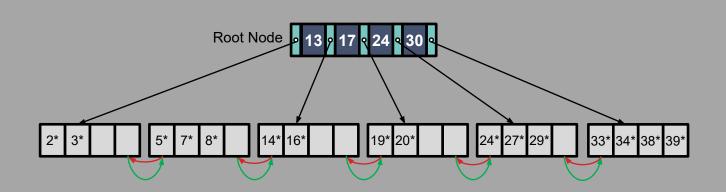

- Find the correct leaf
  - Split leaf if there is not enough room
  - Redistribute entries evenly

# Inserting 8\* into a B+ Tree: Split Leaf, cont

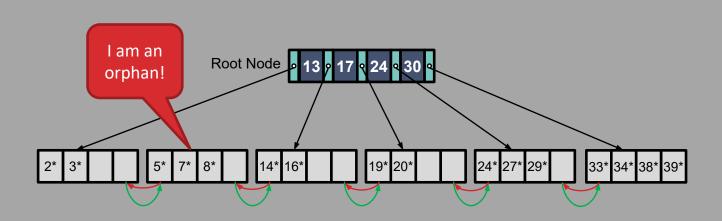

- Find the correct leaf
  - Split leaf if there is not enough room
  - Redistribute entries evenly
  - Fix next/prev pointers

## Inserting 8\* into a B+ Tree: Fix Pointers

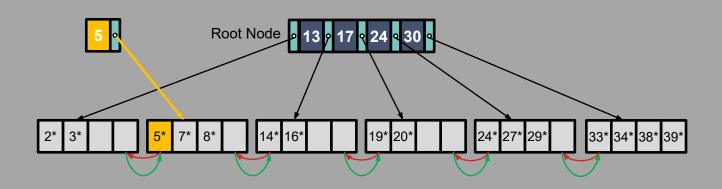

- Find the correct leaf
  - Split leaf if there is not enough room
  - Redistribute entries evenly
  - Fix next/prev pointers

# Inserting 8\* into a B+ Tree: Mid-Flight

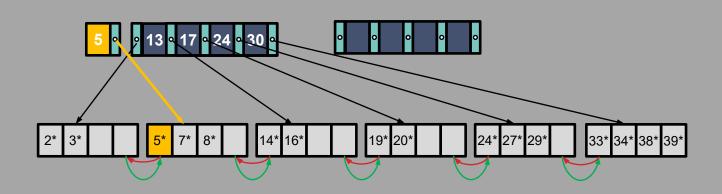

Something is still wrong!

# Inserting 8\* into a B+ Tree: Copy Middle Key

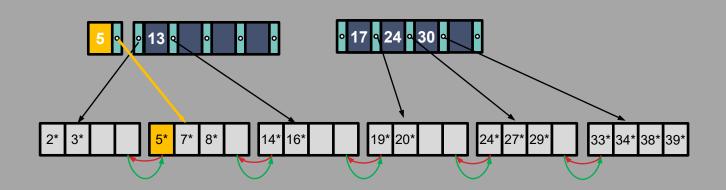

- Copy up from leaf the middle key
- No room in parent? Recursively split index nodes

#### Inserting 8\* into a B+ Tree: Split Parent, Part 1

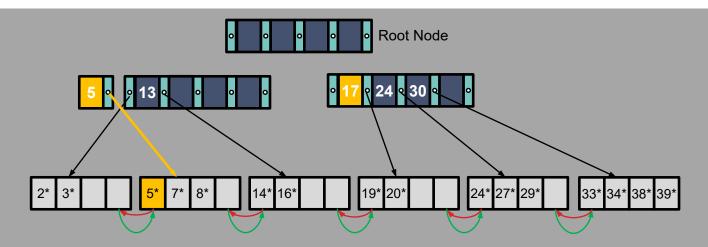

- Copy up from leaf the middle key
- No room in parent? Recursively split index nodes
  - Redistribute the rightmost d keys

#### Inserting 8\* into a B+ Tree: Split Parent, Part 2

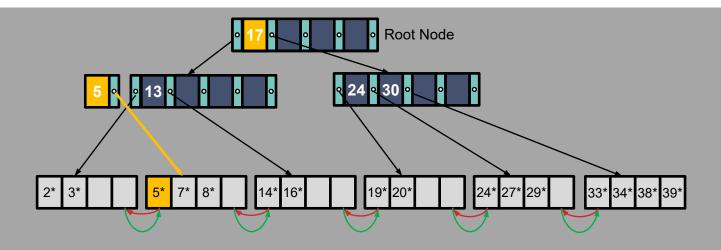

- Copy up from leaf the middle key
- No room in parent? Recursively split index nodes
  - Redistribute the rightmost d keys

## Inserting 8\* into a B+ Tree: Root Grows Up

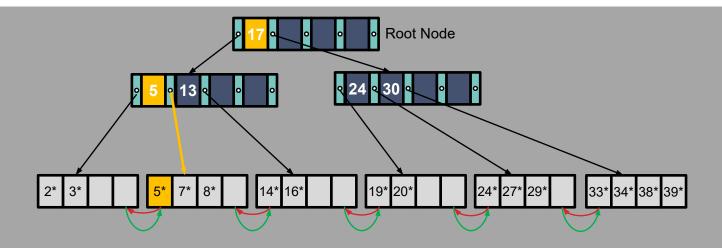

- Push up from interior node the middle key
  - Now the last key on left
- No room in parent? Recursively split index nodes
  - Redistribute the rightmost d keys

#### Inserting 8\* into a B+ Tree: Root Grows Up, Pt 2

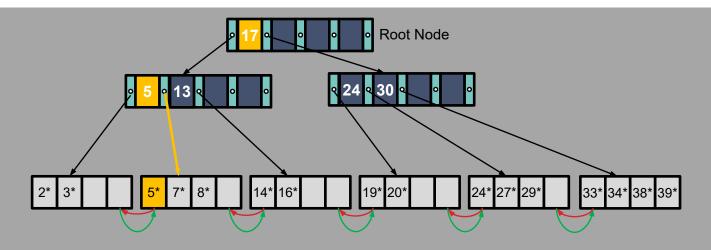

- Recursively split index nodes
  - Redistribute right d keys
  - Push up middle key

#### Inserting 8\* into a B+ Tree: Root Grows Up, Pt 3

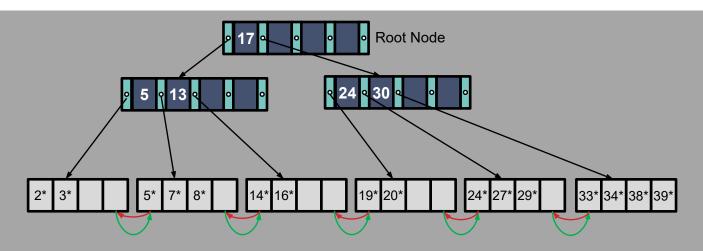

- Recursively split index nodes
  - Redistribute right d keys
  - Push up middle key

# Copy up vs Push up!

- Notice:
  - The leaf entry (5) was copied up
  - The index entry (17) was pushed up

# Inserting 8\* into a B+ Tree: Final

- Check invariants
- Key Invariant:
  - Node[..., (K<sub>L</sub>, P<sub>L</sub>), ...] →
    K<sub>L</sub><= K for all K in P<sub>L</sub> Sub-tree
- Occupancy Invariant:
  - d <= # entries <= 2d</li>

## B+ Tree Insert: Algorithm Sketch

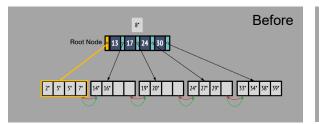

- Find the correct leaf L.
- 2. Put data entry onto L.
  - If L has enough space, done!
  - Else, must split L (into L and a new node L2)
    - Redistribute entries evenly, copy up middle key
    - Insert index entry pointing to L2 into parent of L.

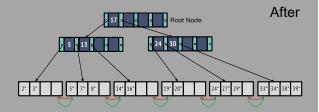

### B+ Tree Insert: Algorithm Sketch Part 2

- Step 2 can happen recursively
  - To split index node, redistribute entries evenly, but push up middle key. (Contrast with leaf splits)
- Splits "grow" tree; root split increases height.
  - Tree growth: gets wider or one level taller at top.

#### Before and After Observations

- Notice that the root was split to increase the height
  - Grow from the root not the leaves.
  - All paths from root to leaves are equal lengths
- Does the occupancy invariant hold?
  - Yes! All nodes (except root) are at least half full
  - Proof?

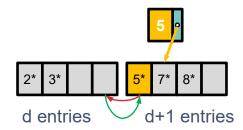

# Splitting a Leaf

- Start with full leaf (2d) entries (let d = 2)
  - Add a 2d + 1 entry (8\*)

- Split into leaves with (d, d+1) entries
  - Copy key up to parent
- Why copy key and not push key up to parent?

# Splitting an Inner Node

- Start with full interior node (2d) entries: (let d = 2)
  - Add a 2d + 1 entry

- Split into nodes with (d, d+1) entries
  - Push key up to parent

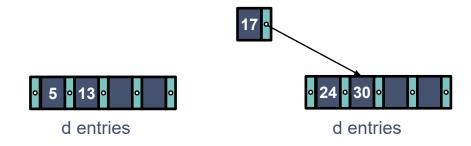

# Splitting an Inner Node Pt 2

- Start with full interior node (2d) entries: (let d = 2)
  - Add a 2d + 1 entry

- Split into nodes with (d, d) entries
  - Push key up to parent

## Splitting an Inner Node Pt 3

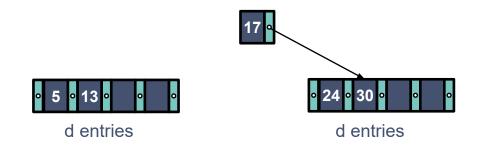

- Start with full interior node (2d) entries: (let d = 2)
  - Add a 2d + 1 entry

- Why push not copy?
  - Routing key not needed in child

Occupancy invariant holds after split

- Split into nodes with (d, d) entries
  - Push key up to parent

#### **Nice Animation Online**

- Great animation online of B+ Trees
- One small difference to note
  - Upon deletion of leftmost value in a node, it updates the parent index entry
  - Incurs unnecessary extra writes

#### **B+-TREE DELETION**

### We will skip deletion

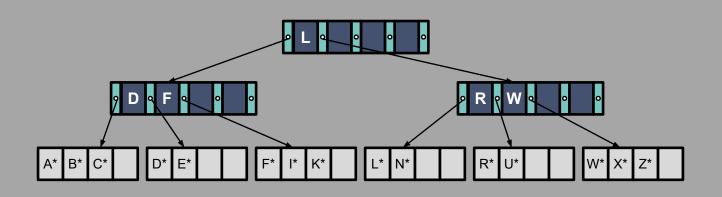

- In practice, occupancy invariant often not enforced
- Just delete leaf entries and leave space
- If new inserts come, great
  - This is common
- If page becomes completely empty, can delete
  - Parent may become underfull
  - That's OK too
- Guarantees still attractive: log<sub>F</sub>(max size of tree)

#### **BULK LOADING B+-TREES**

#### Bulk Loading of B+ Tree Part 1

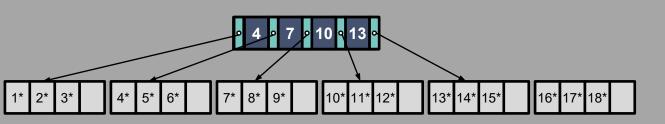

- Suppose we want to build an index on a large table
- Would it be efficient to just call insert repeatedly
  - No ... Why not?
  - Random Order: CLZARNDXEKFWIUB. Order 2.
  - Try it: Interactive demo

# Bulk Loading of B+ Tree Part 2

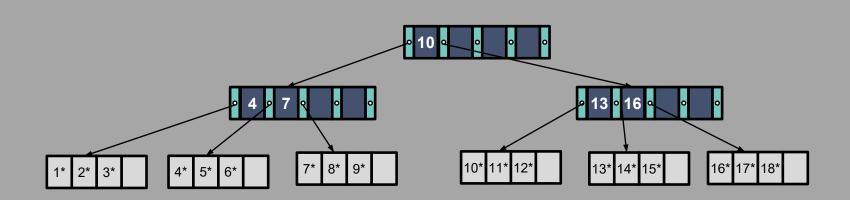

- Constantly need to search from root
- Leaves and internal nodes mostly half-empty
- Modifying random pages: poor cache efficiency

# Smarter Bulk Loading a B+ Tree

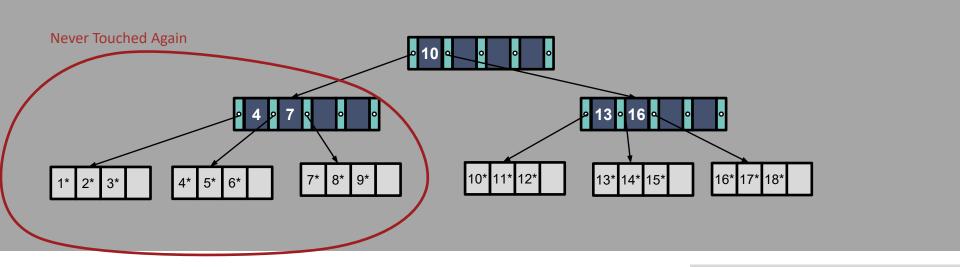

- Sort the input records by key:
  - 1\*, 2\*, 3\*, 4\*, ...
  - We'll learn a good disk-based sort algorithm soon!
- Fill leaf pages to some fill factor (e.g. ¾)
  - Updating parent until full

# Smarter Bulk Loading a B+ Tree Part 2

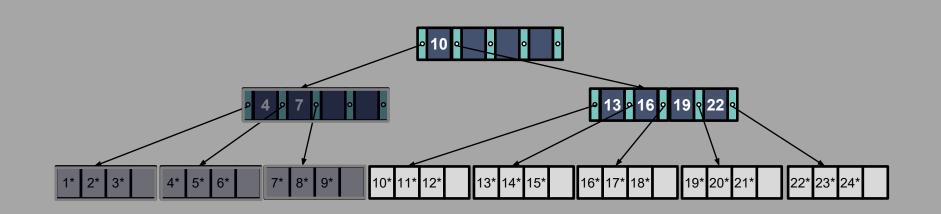

- Sort the input records by key:
  - 1\*, 2\*, 3\*, 4\*, ...
- Fill leaf pages to some fill factor (e.g. ¾)
  - Update parent until full
  - Then split parent (50/50) and copy to sibling

# Smarter Bulk Loading a B+ Tree Part 3

- Lower left part of the tree is never touched again
- Occupancy invariant maintained

# Smarter Bulk Loading a B+ Tree Part 4

- Sort the input records by key:
  - 1\*, 2\*, 3\*, 4\*, ...
- Fill leaf pages to some fill factor (e.g. ¾)
  - Update parent until full
  - Then split parent

# Summary of Bulk Loading

- Option 1: Multiple inserts
  - Slow
  - Does not give sequential storage of leaves
- Option 2: Bulk Loading
  - Fewer I/Os during build. (Why?)
  - Leaves will be stored sequentially (and linked, of course)
  - Can control "fill factor" on pages.

# Summary

- ISAM is a static structure
  - Only leaf pages modified; overflow pages needed
  - Overflow chains can degrade performance unless size of data set and data distribution stay constant

#### B+ Tree is a dynamic structure

- Inserts/deletes leave tree height-balanced; log<sub>E</sub>N cost
- High fanout (F) means depth rarely more than 3 or 4.
- Almost always better than maintaining a sorted file.
- Typically, 67% occupancy on average
- Usually preferable to ISAM; adjusts to growth gracefully.

# Summary Cont.

- Bulk loading can be much faster than repeated inserts for creating a B+ tree on a large data set.
- B+ tree widely used because of its versatility
  - One of the most optimized components of a DBMS.
  - Concurrent Updates
  - In-memory efficiency
