Markov Decision Process

- Markov decision processes formally describe an environment for reinforcement learning
- Where the environment is fully observable
- i.e. The current state completely characterizes the process
- Almost all RL problems can be formalized as MDPs, e.g.
 - Optimal control primarily deals with continuous MDPs
 - Partially observable problems can be converted into MDPs
 - Bandits are MDPs with one state

Markov Property

Definition

A state S_t is Markovian if and only if

$$\mathbb{P}[S_{t+1}|S_t] = \mathbb{P}[S_{t+1}|S_1,\ldots,S_t]$$

- "The future is independent of the past given the present"
- The state captures all relevant information from the history
- Once the state is known, the history may be thrown away
- i.e. The state is a sufficient statistic of the future

Markov Chain

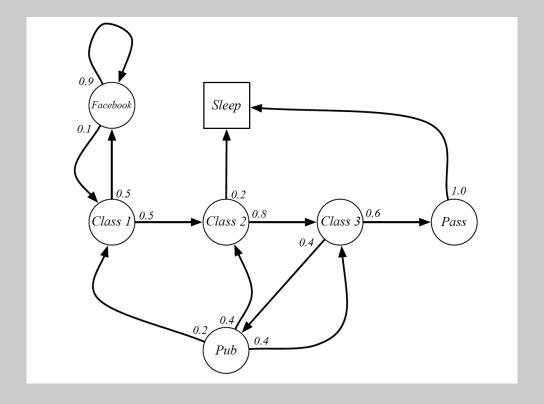

Definition

A discrete-time Markov chain is a tuple $\langle S, P \rangle$

- ullet ${\cal S}$ is a (finite) set of states
- ullet $\mathcal P$ is a state transition probability matrix

$$\mathcal{P}_{s,s'} = \mathbb{P}[S_{t+1} = s' | S_t = s]$$

Markov Reward Process

A Markov reward process is a Markov chain with values.

Definition

A Markov Reward Process is a tuple $<\mathcal{S},\mathcal{P},\mathcal{R},\gamma>$

- ullet S is a (finite) set of states
- ullet ${\cal P}$ is a state transition probability matrix

$$\mathcal{P}_{s,s'} = \mathbb{P}[S_{t+1} = s' | S_t = s]$$

ullet $\mathcal R$ is a reward function,

$$\mathcal{R}_s = \mathbb{E}[R_{t+1}|S_t = s]$$

ullet γ is a discount factor, $\gamma \in [0,1]$

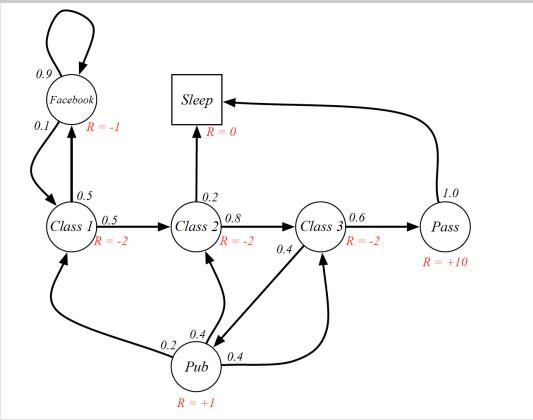

Ziyu Shao (ShanghaiTech)

11/80

Example: Student MRP

Return

Definition

The return G_t is the total discounted reward from time-step t.

$$G_t = R_{t+1} + \gamma R_{t+2} + \ldots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$$

- ullet The discount $\gamma \in [0,1]$ is the present value of the future rewards
- The value of receiving reward R after k+1 time-steps is $\gamma^k R$.
- This values immediate reward above delayed reward.
 - $ightharpoonup \gamma$ close to 0 leads to "myopic" evaluation
 - $ightharpoonup \gamma$ close to 1 leads to "far-sighted" evaluation

Ziyu Shao (ShanghaiTech)

Lecture 7: Markov Decision Proces

May 08 & 10, 2021

13 / 80

Why Discount?

Most Markov reward and decision processes are discounted. Why?

- Mathematically convenient to discount rewards
- Avoids infinite returns in cyclic Markov processes
- Uncertainty about the future may not be fully represented
- If the reward is financial, immediate rewards may earn more interest than delayed rewards
- Animal & human behavior shows preference for immediate reward
- It is sometimes possible to use undiscounted Markov reward processes (i.e. $\gamma=1$), e.g. if all sequences terminate.

Value Function

The value function v(s) gives the long-term value of state s

Definition

The state value function v(s) of an MRP is the expected return starting from state s

$$v(s) = \mathbb{E}[G_t \mid S_t = s]$$

Bellman Equation for MRPs

The value function can be decomposed into two parts:

- immediate reward R_{t+1}
- discounted value of successor state $\gamma v(S_{t+1})$

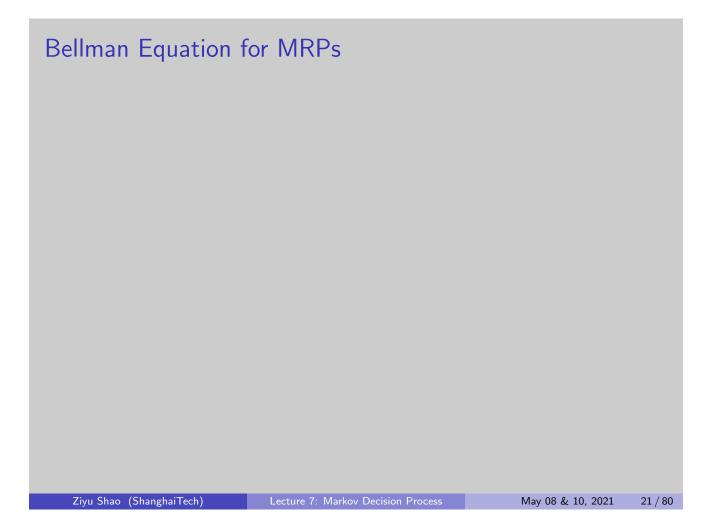

$$v(s) = \mathbb{E}[G_t \mid S_t = s]$$

$$= \mathbb{E}[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots \mid S_t = s]$$

$$= \mathbb{E}[R_{t+1} + \gamma (R_{t+2} + \gamma R_{t+3} + \dots) \mid S_t = s]$$

$$= \mathbb{E}[R_{t+1} + \gamma G_{t+1} \mid S_t = s]$$

$$= \mathbb{E}[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s]$$

Bellman Equation for MRPs

Bellman Equation for MRPs

$$v(s) = \mathbb{E}\left[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s\right]$$

$$v(s) \leftrightarrow s$$

$$v(s') \leftrightarrow s'$$

$$v(s) = \mathcal{R}_s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'} v(s')$$

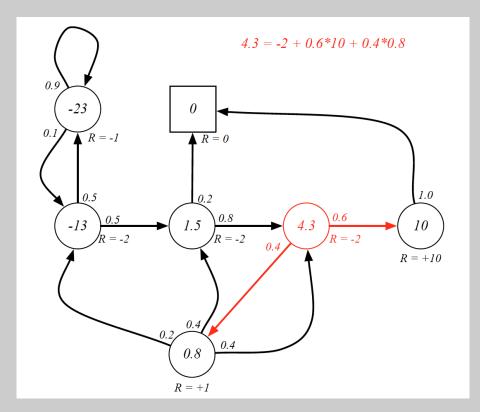

Ziyu Shao (ShanghaiTech)

Example: Bellman Equation for Student MRP

Bellman Equation in Matrix Form

The Bellman equation can be expressed concisely using matrices,

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$

where \mathbf{v} is a column vector with one entry per state

$$\begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix} = \begin{bmatrix} \mathcal{R}_1 \\ \vdots \\ \mathcal{R}_n \end{bmatrix} + \gamma \begin{bmatrix} \mathcal{P}_{11} & \cdots & \mathcal{P}_{1n} \\ \vdots & \ddots & \vdots \\ \mathcal{P}_{n1} & \cdots & \mathcal{P}_{nn} \end{bmatrix} \begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix}$$

Ziyu Shao (ShanghaiTech)

Lecture 7: Markov Decision Process

May 08 & 10, 2021

25 / 80

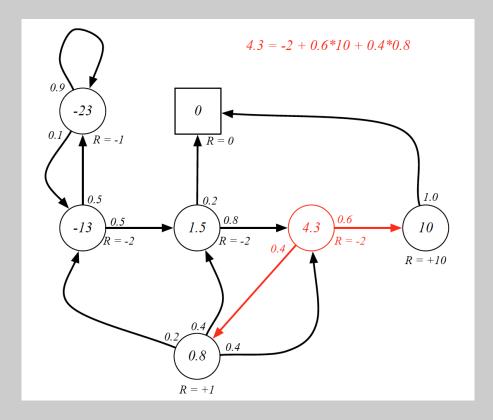

Solving the Bellman Equation

- The Bellman equation is a linear equation
- It can be solved directly:

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$
 $(I - \gamma \mathcal{P}) \mathbf{v} = \mathcal{R}$
 $\mathbf{v} = (I - \gamma \mathcal{P})^{-1} \mathcal{R}$

- Computational complexity is $O(n^3)$ for n states
- Direct solution only possible for small MRPs
- There are many iterative methods for large MRPs, e.g.
 - Dynamic programming
 - Monte-Carlo evaluation
 - Temporal-Different learning

Markov Decision Process

A Markov decision process (MDP) is a Markov reward process with decisions. It is an environment in which all states are Markovian.

Definition

A Markov Decision Process is a tuple $< S, A, P, R, \gamma >$

- ullet S is a (finite) set of states
- \bullet \mathcal{A} is a finite set of actions
- ullet ${\cal P}$ is a state transition probability matrix

$$\mathcal{P}_{s,s'}^{a} = \mathbb{P}[S_{t+1} = s' | S_t = s, A_t = a]$$

 \bullet \mathcal{R} is a reward function,

$$\mathcal{R}_s^a = \mathbb{E}[R_{t+1}|S_t = s, A_t = a]$$

ullet γ is a discount factor, $\gamma \in [0,1]$

Policy

Definition

A policy π is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}[A_t = a \mid S_t = s]$$

- A policy fully defines the behavior of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are stationary (time-independent), $A_t \sim \pi(\cdot|S_t), \forall t>0$.

Policy

- Given an MDP $\mathcal{M} = <\mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma>$ and a policy π
- The state sequence S_1, S_2, \ldots is a Markov process $<\mathcal{S}, \mathcal{P}^\pi>$
- The state and reward sequence $S_1, R_2, S_2 \dots$ is a Markov reward process $< S, \mathcal{P}^{\pi}, \mathcal{R}^{\pi}, \gamma >$
- where

$$\mathcal{P}^{\pi}_{s,s'} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{P}^{a}_{s,s'}$$

$$\mathcal{R}^{\pi}_s = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{R}^a_s$$

Value Function

Definition

The state-value function $v_{\pi}(s)$ of an MDP is the expected return starting from state s, and then following policy π

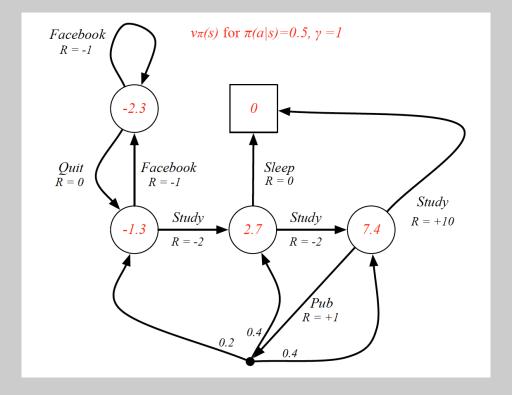

$$v_{\pi}(s) = \mathbb{E}_{\pi}[G_t \mid S_t = s]$$

Definition

The action-value function $q_{\pi}(s,a)$ is the expected return starting from state s, taking action a, and then following policy π

$$q_{\pi}(s, a) = \mathbb{E}_{\pi}[G_t \mid S_t = s, A_t = a]$$

Bellman Expectation Equation

The state-value function can again be decomposed into immediate reward plus discounted value of successor state,

$$v_{\pi}(s) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s \right]$$

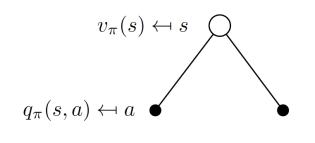

The action-value function can similarly be decomposed,

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a \right]$$

Bellman Expectation Equation (Matrix Form)

The Bellman expectation equation can be expressed concisely using the induced MRP,

$$\mathbf{v}_{\pi} = \mathcal{R}^{\pi} + \gamma \mathcal{P}^{\pi} \mathbf{v}_{\pi}$$

with direct solution

$$v_{\pi} = (I - \gamma \mathcal{P}^{\pi})^{-1} \mathcal{R}^{\pi}$$

Example: Bellman Expectation Equation (Matrix Form)

Optimal Value Function

Definition

The optimal state-value function $v_*(s)$ is the maximum value function over all policies

$$v_*(s) = \max_{\pi} v_{\pi}(s)$$

The optimal action-value function $q_*(s,a)$ is the maximum action-value function over all policies

$$q_*(s,a) = \max_{\pi} q_{\pi}(s,a)$$

- The optimal value function specifies the best possible performance in the MDP.
- An MDP is "solved" when we know the optimal value function.

Optimal Policy

Define a partial ordering over policies

$$\pi \geq \pi'$$
 if $v_{\pi}(s) \geq v_{\pi'}(s)$, $\forall s$

Theorem

For any Markov Decision Process

- There exists an optimal policy π_* that is better than or equal to all other policies, $\pi_* \geq \pi, \forall \pi$
- All optimal policies achieve the optimal value function, $v_{\pi_*}(s) = v_*(s)$
- All optimal policies achieve the optimal action-value function, $q_{\pi_*}(s,a) = q_*(s,a)$

Finding an Optimal Policy

An optimal policy can be found by maximizing over $q_*(s, a)$,

$$\pi_*(a|s) = egin{cases} 1 & ext{if } a = rg \max_{a \in \mathcal{A}} q_*(s,a) \ 0 & ext{otherwise} \end{cases}$$

- There is always a deterministic optimal policy for any MDP
- If we know $q_*(s, a)$, we immediately have the optimal policy

75 / 80

Solving the Bellman Optimality Equation in General

- Bellman Optimality Equation is non-linear
- No closed form solution (in general)
- Many iterative solution methods
 - Value Iteration
 - Policy Iteration
 - Q-learning
 - Sarsa

Solving the Bellman Optimality Equation

- Finding an optimal policy by solving the Bellman Optimality Equation requires the following:
 - accurate knowledge of environment dynamics
 - we have enough space and time to do the computation
 - the Markov Property
- How much space and time do we need?
 - polynomial in number of states
 - ▶ BUT, number of states is often huge
 - So exhaustive sweeps of the state space are not possible

Ziyu Shao (ShanghaiTech)

77 / 80

Approximation and Reinforcement Learning

- RL methods: Approximating Bellman optimality equations
- Balancing reward accumulation and system identification (model learning) in case of unknown dynamics
- The on-line nature of reinforcement learning makes it possible to approximate optimal policies in ways that put more effort into learning to make good decisions for frequently encountered states, at the expense of less effort for infrequently encountered states.
